

# Low-cost Wireless sensor network system for micro-climate monitoring

Mark Neal, Aberystwyth University  
mjn@aber.ac.uk

# What Syngenta want

- Greenwash?
- Originally:
  - Micro-climate monitoring
  - Bio-diversity
  - Field-margins
- Now:
  - Crop growth monitoring
  - Effect of micro-climate within fields

# Parameters

- Air

- Temperature
- Humidity
- Pressure

- Wind

- Speed and direction

Carbon Dioxide

Methane

Rainfall

- Soil

- Temperature
- Humidity

- Light

- “Intensity” (ideally PAR)
- Measure of canopy density
- Senescence

# Sensors

- Cheap! (mostly)
- Hobby quality has to be good enough
  - DHT 22 has 0.1C resolution (around 0.4C accuracy)
  - Soil probe similar (slightly more accurate)
- Rowind is lovely but...
  - Expensive
  - Power-hungry

# Light sensors

- Again “hobby” quality
- Two RGB sensors:
  - ISL29125 (intersil)
  - TCS34725 (Texas)
- Just photodiodes with RGB masks
- TCS board has a white LED as well
- Why two types?

**FIGURE 5. NORMALIZED SPECTRAL RESPONSE FOR AMBIENT LIGHT SENSING**

**FIGURE 6. RADIATION PATTERN**

From intersil (ISL29125, bottom) and Texas datasheets (TCS34725, top)

# How to get the most from the light sensors?

- RGB readings at face-value
  - Can separate grossly different colours with single readings
  - Quite noisy, but with multiple reads and taking medians can discriminate more finely
- Calibration?
  - Can I afford the time?
  - What will I gain?
- Exploit variability?
  - Bio-diversity (identical sensors)
  - Crops (heterogeneous sensors?)
- Filtering strategies (open to suggestions!)
  - Add rejection band filter?

# Data transmission

- Pretty low bandwidth
  - Expecting ~100 bytes per station per minute
- Encoded as plain ASCII
  - Much easier to debug
  - Simple to store and process
- Data content
  - 4 x Temp and Humidity
  - 3 x Light

# Data transmission

- 433MHz vs 2.4GHz
  - RFM69
  - Xbee
  - 802.11
- Cost
- Range
- Data rates
- Power consumption

# Moteino

- Arduino compatible with a 433MHz radio module built-in
  - Range reliably ~500m
  - Significantly more with some tweaking
  - Line-of-sight (pretty much)
- Really easy to get going with
  - Nice libraries
- Can do addressing, packet-filtering etc...
- No routing/meshing built-in
- Just used for simple point-to-point at present

# Moteino facilities

- Provides easy IO (just like an Arduino UNO)
- USB programmable
- Nice library provides access to the radio module
- Radio comms is just calling simple functions
- Very quick to get started and generate “cut-and-paste” functionality
- Unregulated frequency (and not in the 2.4GHz band) which is generally very reliable
- Used this on a balloon launch last year and got 2650m using a directional antenna and stock example code

# Adaptive algorithms for controlling data rate and sampling regime

- Use environment feedback to
  - Increase sampling frequency
  - Decrease sampling frequency
  - Prioritise particular sensors
  - Prioritise particular parts of the network
- Use external input in a similar way
  - Human intervention
  - Weather station data
  - Weather forecast

# Conclusion

- Building small, low-power, long-lived systems has never been
  - Easier
  - Cheaper
- What they lack in precision/accuracy/repeatability they can make up for in other ways
- They offer ways to study things that are genuinely novel
  - But also require a bit of a side-step in the way you think
- Communication technologies can be very cheap, especially for low data rates
